Abstract: Colorectal cancer syndrome has been one of the greatest concerns in the world, particularly in developed countries. Several epidemiological studies have shown that dyslipidemia may be associated with the progression of intestinal cachexia, which is involved in blood lipid metabolism, dyslipidemia. In the present study, we aimed to explore the function of intestinal cholesterol absorption in the Apc\textsuperscript{Min/+} mouse model using an intestinal lipid absorption test. We found that both triglyceride (TG) and total cholesterol (TC) uptake were inhibited in the intestine of Apc\textsuperscript{Min/+} mice with age and the intestinal peroxisome proliferator-activated receptor α (PPARα) downregulated the processes of β-oxidation, oxidative stress response, and cholesterol absorption in APC-deficient mice. In addition, reduced expression levels of farnesoid X receptor (FXR) and apical sodium-dependent bile acid transporter (ASBT) indicated that bile acid metabolism might be associated with intestinal cholesterol absorption in Apc\textsuperscript{Min/+} mice. Thus, our data suggested that the intestine plays an essential role in cholesterol uptake and that bile acid metabolism seems to cause a decrease in intestinal cholesterol uptake in Apc\textsuperscript{Min/+} mice.

Keywords: Adenomatous polyposis coli (APC), cholesterol absorption, dyslipidemia, peroxisome proliferator-activated receptor α (PPARα), bile acid

Introduction

Colorectal cancer (CRC) syndrome has been one of the greatest concerns in the world, particularly in developed countries [1]. A classic animal model of human familial adenomatous polyposis (FAP) is the C57BL/6J-Apc\textsuperscript{Min/+} mouse, and this mouse has a truncated mutation in the adenomatous polyposis coli (APC) gene, which results in multiple intestinal adenoma polyps and is associated with the loss of muscle and fat accompanying hyperlipidemia [2, 3]. Hyperlipidemia has been reported to be closely associated with the development of intestinal adenoma polyps in the Apc\textsuperscript{Min/+} mouse [4]. Previous studies have shown that a low level of intestinal lipoprotein lipase (LPL) mRNA expression may be involved in dyslipidemia and tumor progression [2]. However, what we often ignore is the role of the small intestine in the process of blood lipid metabolism.

Epithelial cells are an important part of the lipid balance in the intestine. Not only can epithelial cells of the small intestine absorb approximately 95% triglycerides (TGs), but they can also store TGs within cytosolic lipid droplets (CLDs) [5, 6]. In addition, the absorbed TGs are decomposed in the lumen of the gut, resulting in FFAs that are activated, esterified and released into lymphatic circulation [7, 8]. CLDs play a core role in the control of enterocyte triglyceride-rich lipoprotein (TRL) secretion [9].

Previous studies have shown that peroxisome proliferator-activated receptor α (PPARα) can regulate the serum level of TGs in Apc\textsuperscript{Min/+} mice through administrating the PPARα ligand bezafibrate [2]. Interestingly, recent studies have emphasized the importance of PPARα in regulating several important processes such as β-oxidation, the oxidative stress response and cholesterol absorption in the murine small

Thus, whether PPARα signaling regulates intestinal cholesterol absorption in ApcMin/+ mice and the exact mechanism of its action are unclear. Therefore, we explored the intestinal cholesterol absorption ability of ApcMin/+ mice using an intestinal lipid absorption test. The aim of this study was to reveal the potential reason for lipid absorption abnormalities in the intestine of ApcMin/+ mice.

Materials and methods

Animals

Four- to five-week-old wild-type male C57BL/6J (WT, n=20) and mutant male C57BL/6J-ApcMin/+ (ApcMin/+; Min, n=20) mice were purchased from the Nanjing Biomedical Research Institute of Nanjing University (Nanjing, China). The mice were provided standard rodent chow and water ad libitum and housed in cages (≤5 mouse per cage) that were placed in an SPF animal facility with the laboratory temperature maintained at 22°C and 40-60% humidity with a 12:12 light:dark cycle. All animal welfare and experimental procedures were performed strictly according to the National Institutes of Health guide for the care and use of laboratory animals (NIH Publications No. 8023, revised 1978). In addition, the procedures were approved by the Institutional Animal Care and Use Committee of Jilin University under approved protocol number 201707025.

Intestinal lipid absorption test

At the periods of 8, 14 and 20 weeks, the mice were fasted for 4 hours starting at 05:00 prior to undergoing the intestinal lipid absorption test. Thirty minutes after injection, the mice were gavaged with 200 µl of olive oil to assess dietary fat absorption. Blood was sampled via the tail vein at the baseline of 0 h and at 3 and 6 h, and the blood was centrifuged at 2000×g for 10 minutes at 4°C. Fasting plasma total cholesterol (TC) and triglycerides (TGs) were analyzed using commercial kits from Biosino (Beijing, China) [13].

Intestinal permeability assay

FITC-dextran (4 kDa, Sigma, USA) was administered by oral gavage (60 mg/100 g body weight, 40 mg/mL) to the fasted mice. After 1 hour, blood was collected, stored on ice in the dark and centrifuged 1000×g for 15 minutes at 4°C. The serum was diluted with the same volume of PBS, and the fluorescence intensity was measured using a fluorescence spectrophotometer (λex: 485 nm; λem: 535 nm, Infinite 200 Pro, Tecan, Switzerland) [14].

Gut transit test

Overnight-fasted mice were gavaged with 200 µl of Evans blue suspension (5% Evans blue and 5% gum arabic in PBS). Afterward, the mice had free access to food and water, and the time until the Evans blue was detected in the feces was recorded [13].

Oil red O staining

For oil red O staining, the jejuncum was isolated and fixed in 4% neutral-buffered formalin (Carl

Plasma triglyceride (TG) and total cholesterol (TC) levels were determined by tail vein nick in the Apc\textsuperscript{Min/+} and WT mice at 0-, 3- and 6-h time points at 8, 14 and 20 weeks (n=5). Data are the mean of three independent experiments (an average of five readings was conducted for each sample), Mean ± SEM. The differences between the mean values were assessed by Student’s t-tests and analyzed using GraphPad Prism software 7.0. *P<0.05; **P<0.01; ***P<0.001 and ns, not significant.

Roth GmbH, Vienna, Austria). Serial sections (5 μm) of the jejunum were removed and stained with oil red O and Mayer’s hematoxylin. Microscopic images were taken using a Nikon Eclipse E600 equipped with a Nikon Digital Sight DS-U1 unit (Spach Optics Inc., New York, NY). Oil Red O staining of the jejunum was performed on frozen sections using standard protocols [15].

Real-time quantitative PCR analysis

Total RNA from the jejunum of mice was extracted using TRNzol-A reagent and reverse transcribed to cDNA according to the manufacturer’s instructions using a FastQuant RT kit (Tiangen, Beijing, China). The primers used for gene amplification are presented in Table 1. qPCR was performed using a Bio-RadiQ5 instrument (Bio-Rad, USA). The 2\textsuperscript{-ΔΔCt} method was used to determine related gene expression, which was normalized to the amount of GAPDH mRNA. All experiments were repeated three times
Intestinal cholesterol absorption in colorectal cancer

for each gene and the data are expressed as the mean ± SEM.

**Western blotting analysis**

Equal amounts of protein samples were loaded into each lane of the gel for SDS-PAGE, followed by immunoblotting on a nitrocellulose membrane (NC, Boster, China). Then, the membranes were incubated with an LPL antibody and a PPARα antibody (Boster, China) at 4°C. The membranes were incubated with a secondary antibody (GAPDH, Beyotime, China) and imaged using a BeyoECL Plus kit (Beyotime, Beijing, China). To confirm the reproducibility of the results, at least three mice per group were used in each stage or treatment in this study.

**Statistical analysis**

All the data were analyzed using GraphPad Prism software 7.0 (La Jolla, CA, USA). The variation was analyzed by Student’s t-tests, and the results are expressed as the Mean ± SEM. *P* values <0.05 were considered statistically significant.

**Results**

The intestines that were examined in our study were taken from Apc<sup>Min/+</sup> mice and classified as noncachectic (8 weeks of age), precachectic (14 weeks of age) and severely cachectic (20 weeks of age).

**Gut barrier dysfunction in Apc<sup>Min/+</sup> mice with colon cancer cachexia**

To objectively assess intestinal dysfunction in Apc<sup>Min/+</sup> mice, the permeability of FITC-dextran (4 kDa) was investigated. It was remarkable that the concentration of FITC-dextran increased by nearly 1.5-fold at 14 weeks of age (Apc<sup>Min/+</sup> mouse group versus wild-type mouse group: 1.35 ± 0.29 ng/μL versus 0.96 ± 0.13 ng/μL, *P*<0.05) and approximately 6.5-fold at 20 weeks of age (Apc<sup>Min/+</sup> mouse group versus wild-type mouse group: 6.19 ± 0.56 ng/μL versus 0.98 ± 0.2 ng/μL, *P*<0.001; Figure 1A). We noted that the time that Evans blue appeared in the feces gradually increased in the gut transit test at 8, 14 and 20 weeks of age (Apc<sup>Min/+</sup> mouse group versus wild-type mouse group: 123.4 ± 10.71 minutes versus 116.57 ± 12.74 minutes, *P*<0.05; 144.6 ± 7.6 minutes versus 121.71 ± 10.7 minutes, *P*<0.001; 183 ± 14.2 minutes versus 134.43 ± 8.42 minutes, *P*<0.001; respectively; Figure 1B). During the deterioration of cachexia (red arrow), significant intestinal inflammation (black arrow) appeared at 20 weeks of age but not at 14 weeks of age in the Apc<sup>Min/+</sup> mice (Figure 1C). A remarkable lactescence in Apc<sup>Min/+</sup> mice indicated that the mice had suffered from severe hyperlipidemia (Figure 1D).

**Intestinal lipid absorption inhibition occurs in Apc<sup>Min/+</sup> mice**

To evaluate the intestinal lipid absorption ability of Apc<sup>Min/+</sup> mice, in our study, mice were fasted for 4 h prior to undergoing an intestinal lipid absorption test (Figure 2A). Next, we examined
the levels of serum triglycerides (TGs) and total cholesterol (TC) in Apc\textsuperscript{Min/+} and WT mice at 0-, 3-, and 6-hour time points at 8, 14 and 20 weeks after olive oil gavage, respectively. TG was higher in the Apc\textsuperscript{Min/+} mice than in the WT mice at the 3-hour time point at 14 weeks (Apc\textsuperscript{Min/+} group versus WT group: 4567.55 ± 404.14 mg/dL versus 3541.24 ± 465.15 mg/dL; \(P<0.05\)); however, TG was significantly lower in the Apc\textsuperscript{Min/+} mice than in the WT mice at the 6-hour time point at 14 weeks (Apc\textsuperscript{Min/+} group versus WT group: 5667.14 ± 392.49 mg/dL versus 6305.72 ± 114.70 mg/dL; \(P<0.01\)). In contrast, TG was significantly higher in the Apc\textsuperscript{Min/+} mice than in the WT mice at the 0-hour time point at 20 weeks (Apc\textsuperscript{Min/+} group versus WT group: 1659.99 ± 342.28 mg/dL versus 250.02 ± 62.15 mg/dL; \(P<0.001\)). However, TG was significantly lower in the Apc\textsuperscript{Min/+} group than in the WT group at the 6-hour time point at 20 weeks (Apc\textsuperscript{Min/+} group versus WT group: 5647.90 ± 459.72 mg/dL versus 7758.37 ± 488.01 mg/dL; \(P<0.01\)). Additionally, there was no significant difference between the WT and Apc\textsuperscript{Min/+} mice at 8 weeks, the 0-hour time point at 14 weeks and the 3-hour time point at 20 weeks (Figure 2B). The TC of the Apc\textsuperscript{Min/+} mice was significantly decreased at the 3-hour and 6-hour time points at 20 weeks (Apc\textsuperscript{Min/+} group versus WT group: 269.7 ± 52.14 mg/dL versus 444.08 ± 54.89 mg/dL; 414.32 ± 33.58 mg/dL versus 519.56 ± 43.71 mg/dL; respectively; \(P<0.001\)), and there was no significant difference at 8 and 14 weeks between the two groups (Figure 2C).

**Lipid droplets accumulate in the jejunum of Apc\textsuperscript{Min/+} mice**

We further determined whether the intestinal lipid absorption inhibition resulted in lipid droplets accumulating in Apc\textsuperscript{Min/+} mice. Oil red O staining of the jejunum confirmed that an increased number of lipid droplets accumulated in the Apc\textsuperscript{Min/+} mice than in the WT mice at the 14 and 20 weeks of age and that there was no significant difference at 8 weeks between the two groups (Figure 3). Our results indicate that intestinal lipid absorption inhibition occurs in Apc\textsuperscript{Min/+} mice with age.

**APC deficiency results in the downregulation of intestinal PPAR\(\alpha\) target genes**

To further understand the function of intestinal lipid metabolism in Apc\textsuperscript{Min/+} mice, the expression of PPAR\(\alpha\) target genes was analyzed. As is
Intestinal cholesterol absorption in colorectal cancer

CD36 plays an essential role in the uptake of FFAs and cholesterol from the intestinal lumen and is regulated by PPARα [16, 17]. In our study, decreased CD36, NPC1L1, ABCG5 and ABCA1 mRNA levels might have been involved in the cholesterol absorption inhibition in ApcMin/+ mice. To further determine whether bile acids can regulate cholesterol absorption, we analyzed the expression of intestinal PPARα target genes: β-oxidation, including acyl-CoA oxidase (AOX), acyl-CoA thioesterase 1 (ACOT1), acyl-CoA thioesterase 2 (ACOT2) and acetyl-CoA acyltransferase 2 (ACAA2); oxidative stress response (ROS), including glutathione S-transferase kappa 1 (GSTK1), glutathione S-transferase mu 3 (GSTM3) and glutathione S-transferase theta (GSST); lipid absorption, including Niemann-Pick C1 like-1 (NPC1L1), cluster of differentiation 36 (CD36), microsomal triglyceride transfer protein (MTTP), ATP-binding cassette subfamily A member 1 (ABCA1), ATP-binding cassette subfamily G member 5 (ABCG5) and ATP-binding cassette subfamily G member 8 (ABCG8). The expression of Aox, Acot1, Acaa2, Gstm3, Gsst, Npc1l1, CD36, Mttp, Abca1 and Abcg5 was markedly downregulated in the jejunum of the ApcMin/+ mice. There was no change in the expression of Acot2, Gstk1 and Abcg8 between the two groups (Figure 4B-D). The results indicated that APC is very important for PPARα activation in the jejunum. A schematic diagram of the fatty acid β-oxidation, oxidative stress response, and cholesterol absorption processes in the enterocytes of mice is shown in Figure 5.

Bile acids affect intestinal cholesterol absorption in ApcMin/+ mice

Figure 5. Schematic of fatty acid β-oxidation, oxidative stress response and cholesterol absorption processes in the enterocytes of mouse. The main cholesterol importer NPC1L1 and the cholesterol exporters ABCG5/G8 are located at the apical membrane of enterocytes and facilitate the uptake of cholesterol across the brush border membrane. ACAT2 esterifies the absorbed cholesterol, and MTTP transfers triglycerides and cholesteryl esters to ApoB48 in the smooth ER. The nascent chylomicrons leave the ER, are secreted through the Golgi complex to the basolateral side of the enterocyte and reach the venous circulation through lymphatic vessels. In addition to the chylomicron pathway, a significant portion of intestinal xanthophylls are absorbed through an ABCA1/ApoA1 pathway and may be preferentially delivered to some tissues. The absorption of dietary cholesterol through the apical membrane into enterocytes is associated with β-oxidation and/or oxidative stress response. NPC1L1: Niemann-Pick C1 like-1; ABCG5/G8: ATP-binding cassette subfamily G member 5 and 8; CD36: cluster of differentiation 36; apoB48: apolipoprotein B48; MTTP: microsomal triglyceride transfer protein; ACAT2: acyl-coenzyme A cholesterol acyltransferase 2; ER: endoplasmic reticulum; Golgi: Golgi apparatus; ABCA1: ATP-binding cassette transporter A1; HDL: high-density lipoprotein; AOX: acyl-CoA oxidase; ACOT1/2: acyl-CoA thioesterase 1/2; ACAA2: acetyl-CoA acyltransferase 2; GSTK1: glutathione S-transferase kappa 1; GSTM3: glutathione S-transferase mu 3; GSST: glutathione S-transferase theta; OS: oxidative stress; PPARα: peroxisome proliferator-activated receptor α; FXR: farnesoid X receptor; ASBT: apical sodium-dependent bile acid transporter; SHP: short heterodimer partner.
Intestinal cholesterol absorption in colorectal cancer

Figure 6. Bile acids affected intestinal cholesterol absorption in ApcMin/+ mice. A. FXR and ASBT were measured by qRT-PCR in the intestines of ApcMin/+ and WT mice (n=3). Data are expressed as the mean ± SEM. The differences between the mean values were assessed by Student’s t-tests and analyzed using GraphPad Prism software 7.0. **P<0.01. B. Bile acids may inhibit cholesterol uptake in the intestine of ApcMin/+ mice. Cholesterol uptake is mediated by NPC1L1, CD36, and ABCG5/G8 in enterocytes. PPARα activation reduces cholesterol uptake and bile acids and may reduce FXR activation. FXR inhibits ASBT through reduced SHP activation. NPC1L1: Niemann-Pick C1 Like-1; ABCG5/G8: ATP-binding cassette transporter G5/G8; CD36: cluster of differentiation 36; PPARα: peroxisome proliferator-activated receptor α; FXR: farnesoid X receptor; ASBT: apical sodium-dependent bile acid transporter; SHP: short heterodimer partner.

Lysed the farnesoid X receptor (FXR) and apical sodium-dependent bile acid transporter (ASBT) mRNA levels between the two groups. The expression of FXR and ASBT was significantly downregulated in the jejunum of the ApcMin/+ mice (P<0.01) (Figure 6A). A schematic of bile acid metabolism in the enterocytes of mice is shown in Figure 6B. These data indicated that intestinal APC deficiency can regulate bile acid metabolism.

Discussion

In our preliminary experiment, we demonstrated that ApcMin/+ mice exhibit intestinal cachexia that is associated with the loss of body weight and is accompanied by abnormalities in hepatic lipid metabolism. The intestine is an essential element in the biosynthesis of triglycerides and systemic metabolism [18]. However, research on the intestinal lipid mechanism is still lacking in ApcMin/+ mice.

Our study showed gut barrier dysfunction with hyperlipidemia and tumor growth was present during cachexia. This dysfunction resulted in a significant increase in the permeability of FITC-dextran (4 kDa) in the intestine along with a delay in gut transit with age. Similarly, research by Puppa et al. suggested that glucose tolerance, plasma IL-6, TGs, and body temperature are characteristic of endotoxemia, which is accompanied with a change in gut permeability in ApcMin/+ mice [19]. Another study revealed that some inflammation occurring in intestinal epithelial cells can decrease gut homeostasis [20]. In fact, intestinal lipid absorption plays an essential role in gut lipid homeostasis. Our findings demonstrated that the lipid absorption ability dramatically decreased with age, as shown by marked lipid droplet accumulation in the jejunum of the ApcMin/+ mice.

Current research has shown that intestinal lipid metabolism plays a key role in the health of animals and that changes in lipid absorption may induce related diseases [21]. As is reported, PPARα has an essential role in the progression of intestinal diseases [22]. Thus, we also analyzed the expression of PPARα and related target genes (including genes involved in β-oxidation, the oxidative stress response and cholesterol absorption) in the jejunum. Our results showed that the expression of Aox, Acot1, Aca2, Gstm3, Gsst, Npc1l1, Mttp, Abca1 and Abcg5 was remarkably downregulated in the ApcMin/+ mice. Specifically, during the process of cholesterol absorption, the most obvious change was a significant decrease in CD36, which, as reported, is important in the uptake of free fatty acids (FFAs) and chylomicron formation and secretion from the proximal intestine [23, 24]. In addition, the mRNA levels of the main cholesterol importer NPC1L1 and the cholesterol exporter ABCG5 decreased [25]. Interestingly, the mRNA expression of ABCA1, which is regulated by PPARα and associated with cholesterol absorption and high-density lipoprotein (HDL) production, was downregulated [26]. Therefore, all the results indicated that reduced levels of...
Intestinal cholesterol absorption in colorectal cancer

CD36, NPC1L1, ABCG5 and ABCA1 mRNA might be involved in cholesterol absorption in the jejunum of Apc<sup>Min/+</sup> mouse.

Studies have shown that bile acids, as ligands for the bile acid receptor farnesoid X receptor (FXR), alter the transcription of several genes that are involved in triglyceride synthesis and lipid metabolism [27]. Early clinical studies have found that PPARα regulates bile acid synthesis, bile acid transport and cholesterol metabolism pathways [28]. In addition, PPARα has been confirmed to be activated in the intestine of Apc<sup>Min/+</sup> mice. Furthermore, our results indicated that decreased expression of FXR and ASBT in the jejunum modulates bile acid metabolism in Apc<sup>Min/+</sup> mice. Thus, we speculate that the change in cholesterol absorption might be a consequence of a reduced amount of bile acids in the jejunum of Apc<sup>Min/+</sup> mice.

In conclusion, our data suggested that the intestine plays an essential role in cholesterol uptake and that bile acid metabolism seems to cause a decrease in intestinal cholesterol uptake in Apc<sup>Min/+</sup> mice.
